Research Article

Formulation and Evaluation of Etoricoxib Microbeads for Sustained Drug Delivery

Gurleen Kaur*, Sonia Paliwal
Department of Pharmaceutics, Global Institute of Pharmaceutical Education and Research, Kashipur, Uttarakhand, India.

Abstract
The aim of the study was to develop novel drug design of etoricoxib microbeads for sustained drug delivery by oral route which reduces the dosing frequency. Etoricoxib is a NSAIDs commonly used by patients so to reduce the dosing frequency of drug administration the etoricoxib loaded microbeads were prepared with sodium alginate and calcium chloride in different ratios by ionotropic gelation technique and characterized by FTIR. Drug entrapment efficiency, particle size, swelling index and release profile of the microbeads show that 3.86±0.28% of surface entrapment, drug content 87±0.35%, swelling Index was found to be 80.76. The IR spectrum shows stable character of etoricoxib in the microbeads and revealed an absence of drug polymer interaction. The prepared microbeads were spherical in shape and had a size range of 125±0.02 to 165±0.18 μm, the release of the drug was found to be 64.09±0.24 in F4 formulation among all formulation in 240 minutes which shows that the drug released by sustained effect and shows kinetic release mechanism the formulation F1 shows fickian diffusion and F2, F3 and F4 shows the super-case II transport which depends upon the loss of polymeric chain and the release of drug takes place.

Keywords: Gelling agent, etoricoxib, ionotropic gelation, microbead, NSAIDS.

Introduction
A novel sustained drug delivery system releases the drug in the particular body compartment at the controlled rate required for a specific treatment. Now a day’s drug delivery system uses bio-degradable, biocompatible and natural bio-polymers and are capable of rate-controlling drug release. This system being solid dosage form entrapped by the drug in natural polymer and forming a bead and named as microbeads.

Microbeads are defined as the monolithic sphere distributed the whole matrix as a molecular dispersion of particle and molecular dispersion defined as the drug particle are dispersed in to the continuous phase of one or more than one miscible polymer. The controlled systemic absorption specifically in the intestinal region offers interesting possibilities for the treatment of diseases such as asthma, arthritis or inflammation.

It is a small spherical particle with diameters in the micro-meter range (greater than 0.1μm and less than equal to 5mm) which can vary in chemical composition, size, shape, density, and function. Microbeads are manufactured for specific purposes, including for use in personal care products also such as scrubs, bath products, facial cleaners, toothpastes. They may also be used in industry (e.g., oil and gas exploration, textile printing), other plastic products (anti-slip, anti-blocking applications) and medical applications. Microbeads are small, solid and free flowing particulate carriers containing dispersed drug particles either in solution or crystalline form that allow a sustained release or multiple release profiles of treatment with various active agents without major side effects.

Etoricoxib is a sulfone and pyridine derivative a non-steroidal anti-inflammatory drug (NSAID). Its pharmacological effects are believed to be due to inhibition of cyclooxygenase-2(COX-2) which decreases the synthesis of prostaglandins involved in mediating anti-pyretic, analgesic, and potential antineoplastic properties. It is used for the treatment of rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, chronic low back pain, acute pain and gout used to ease mild to moderate pain and widely considered to be the best tolerated drug.
The objective of present study was to develop a most effective etoricoxib microbeads encapsulated with sodium alginate a gelling agent it promotes better stability with enhanced pharmacological action, improved and better drug release profile of the drug by preparing a suitable etoricoxib microbeads for the treatment of pain and inflammation.

MATERIALS AND METHODS
Etoricoxib was obtained from Balaji drugs, India and sodium alginate was obtained from Central drug house, India. Compatibility of etoricoxib with sodium alginate used to formulate microbeads was established by FTIR. Spectral analysis etoricoxib, chitosan and sodium alginate was carried out to investigate any changes in chemical composition of the drug after combining it with the excipients.

Method of microbeads preparation:
Microbeads are prepared by ionotropic gelation technique by accurately weighing the materials including the drug (Etoricoxib) used, sodium alginate and calcium chloride. To the weighed quantity of sodium alginate distilled water is added to make mucilage paste and allowed for heat for 5-10 minutes in a hot plate on other side, calcium chloride solution is been prepared. The mucilage paste of sodium alginate is stirred in a magnetic stirrer at a suitable speed for several minutes. The drug is dispersed in the mucilage paste of sodium alginate and stirred at suitable speed in the magnetic stirrer. Micro-beads are formed by dropping the sodium alginate and dispersed drug through syringe needle to the calcium chloride solution air dried for some time and finally, micro-beads were filtered and washed thoroughly with distilled water, dried at room temperature subsequently for few hours.

EVALUATION PARAMETERS

Bulk density/ Tapped density
Both bulk density (BD) and tapped density (TD) were determined. A suitable amount of beads was introduced into a 100ml measuring cylinder. After observing its initial volume, the cylinder in the density taper instrument and density is measured according to USP method II (up to 1250 taps). The tapping was continued until no further change in volume was noted.

Hausner’s ratio
It is the ratio of tapped to bulk density and was calculated.

The Angle of Repose
The value of angle of repose was calculated by using the following formula,

\[
\tan \theta = \frac{h}{r}
\]

Where, \( h \) = cone height, \( r \) = radius of circular base formed by the microbeads on the ground.

Particle size
Determination of average particle size of etoricoxib microbeads was carried out by optical microscopy in which stage micrometre was employed. A minute quantity of microbeads was spread on a clean glass slide and average size was determined in each batch.

Percentage Yield
A positive co-relation between the solid content and percentage yield was observed. This may be explained by the fact that, though a constant material is always lost in processing, this loss is proportionately less significant when the solid content is more. The Percentage and theoretical value are determined by which we can calculate the percentage yield.

Drug content
Microbeads were kept in the phosphate buffer 7.4 solution for 24 hours, then filter it. The absorbance of filtrate was taken at \( \lambda_{	ext{max}} \) 284 nm and concentration was determined.

Drug entrapment efficiency
The capture efficiency of microbeads or the percent drug entrapment can be determined by allowing washed microcapsule to lyse. The lysate is then subjected to determination of active constituents as per monograph. The percent encapsulation efficiency (%EE) was calculated using following equation.

\[
\% \text{EE} = \frac{\text{Actual content}}{\text{Theoretical content}} \times 100
\]

In-vitro dissolution study
The in-vitro release studies were carried out for the formulation in dissolution vessel (USP apparatus type-II paddle method) in 900 ml of phosphate buffer 6.8 was placed. The sample was then placed in the vessel and the apparatus was operated for 4 hrs. at 50 rpm. At definite time interval 5ml was withdrawn from the vessel and another 5ml of the blank was added to the vessel. The withdrawn fluid is then filtered and suitable dilution was made. Samples are then analysed under UV Spectrophotometer at 284 nm.

Swelling Index
The weight of the microbeads was taken first and then dissolved in phosphate buffer pH 6.8 for 24 hrs. The excess liquid is removed using blotting paper and the weight of the swollen microspheres is taken. Swelling index is thus calculated using formula:

\[
\text{SI} = \frac{\text{weight of swollen microbeads}}{\text{weight of dried microbeads}} \times \frac{\text{weight of swollen microspheres}}{1}
\]

Loose surface crystal study (LSC)
This study was conducted to estimate the amount of drug present on the surface of the micro beads which showed immediate release in dissolution media. 100mg of micro beads were suspended in 100ml of phosphate buffer (pH 6.8), simulating the dissolution media. The samples were shaken vigorously for 15min in a mechanical shaker. The amount of drug leached out from the surface was analysed spectrophotometrically at 284nm. Percentage of drug released with respect to entrapped drug in the sample was recorded.

RESULTS AND DISCUSSION
The result of FTIR spectrum studies showed that there was no significant interaction between the drug and polymer. In present study four formulations of microbeads were prepared by the means of chitosan and sodium alginate. The prepared formulations were evaluated on different parameters.

From the formulations we observed that BD and TD for all the formulations were found in the range between 0.13 to 0.41 g/ml, 0.20 to 0.34 g/ml.
respectively and formulation F4 was found to be significant drug release character. The percentage of etoricoxib increases as in F4 formulation 87±0.35%. As the amount of polymer in the formulation increases, the drug release increases. The particle size varies from 125±0.02 to 165±0.18µm in all formulations. Loose surface crystal (LSC) study was an important parameter giving an indication of the amount of drug on the surface of the microbeads without proper entrapment. The surface entrapment decreases 3.86±0.28% as a result of increase in drug entrapment 88.72±0.15%. The surface entrapment decreases 3.86±0.28% as a result of increase in drug entrapment 88.72±0.15%. The particle size varies from 125±0.02 to 165±0.18µm, the formulation F4 containing highest amount of sodium alginate which gives the highest swelling index. Loose surface crystal (LSC) study was an important parameter giving an indication of the amount of drug on the surface of the microbeads without proper entrapment. The formulation F4 was found to be the best among all the other formulation because the percentage yield was found to be 80.6% among all formulations. Moreover, the effect of each variable on release characteristic was found to be significant in formulation F4 in 240 minutes the release was found to be 64.092±0.24% as confirmed by data analysis as it shows the super-case II transport which depends upon the loss of polymeric chain and the release of drug takes place. Respectively, the present study can be used to design microbeads of desired release characteristic.
