THE RELATIONSHIP BETWEEN DIABETES MELLITUS AND TUBERCULOSIS IN REVIEW OF PREVALENCE, DIAGNOSTICS AND PREVENTION
Tan Celine, Chai Jia Yee, Muhammad Shahzad Aslam*
School of Traditional Chinese Medicine, Xiamen University Malaysia.

ABSTRACT
Tuberculosis (TB) is a bacterial infection caused by *M. tuberculosis*, also known as *Mycobacterium Tuberculosis*. There is a bidirectional relationship between TB and diabetes, and they both impact the presentation of each other. Diabetes is being increasingly recognized as a risk factor for TB. The expected rise in diabetes cases in developing countries having the brunt of tuberculosis would increase the influence of diabetes on TB in the coming future. The impact and relationship between TB and diabetes will vary across different regions of the world depending on the incidence and prevalence of each condition. Patient education is so important in understanding the disease nature (both TB and diabetes), duration of treatment, side effects of drugs; and complications of disease as well as the promotion of healthy lifestyle choices. The objective of this review is to determine the prevalence, diagnostic and prevention strategy between diabetes mellitus and tuberculosis. The selected studies were identified using Pub Med database. The identified studies define lifestyle as important risk factor that may worsen the progression of the disease. This article also discussed about the prevalence of tuberculosis-diabetes mellitus over a span of 8 years.

Keywords: Diabetes mellitus, risk factors, tuberculosis.

INTRODUCTION
Tuberculosis is a contagious infection that affects lung most efficiently and can also transport through the blood or lymphatic system, TB bacteria can infect almost any part of the body, including lymph nodes, joints, kidneys, and bone. Tuberculosis can spread by droplets of bacteria released into the air by an infected person who coughs, sneezes, talks or sings. Nowadays, TB has become the most prevalent infectious disease in the world. TB is by far the 7th leading cause of the death worldwide, and experts predict that if the disease is not well controlled, it could become the world's leading cause of death by 2050 as mentioned in Figure 1.

People infected with TB will show symptoms of cough, fever, chest pain, loss of appetite, weight loss and others. TB can affect other parts of the body and shows symptoms that depend on the part it affects. For example, it can lead to meningitis if TB affected the brain or infection with the liver or kidney can cause filtration dysfunction, causing blood to enter the urine. People with immune deficiencies caused by the disease are most likely to develop TB. For instance, when a person is infected with HIV, it suppresses the immune system, preventing it from usually suppressing TB bacteria.

Furthermore, people with diabetes, certain cancers, malnutrition, kidney disease, cancer treatments such as chemotherapy or many others can have an increased risk to get TB. TB is common in particular geographic regions, ethnic groups, or age groups. However, it can affect all age groups and all parts of the world. People with diabetes are three times more likely to develop TB. In the interaction between TB and diabetes, the effect of diabetes on TB is more life-threatening. Therefore, the World Health Organization (WHO) defines diabetes as a risk factor for TB7. The main reason for the prevalence of TB in diabetic patient is because the bacteria can grow and multiply easily in the high-sugar environment and often lack vitamins A and B, thus weaken the resistance of respiratory tract, which is conducive to the infection and development of the bacteria. Infected patients with TB, due to symptoms of poisoning and the consumption of nutrients, affect the normal play of islet, causing islet cell malnutrition and atrophy, leading to diabetes.
Aslam et al.

Diabetes is closely related to TB. In recent years, diabetes has been significantly increased with TB, which has become a clinical concern. When the two diseases coexist, the TB is complicated and difficult to treat. As the incidence of diabetes and TB continues to increase, the prevalence of TB has gradually increased, and research on the correlation between the two has increased. Therefore, our objective of this study is to better understand the relationship between diabetes and tuberculosis prevalence, diagnosis and prevention⁹.

METHODOLOGY
By using PubMed database, the author has found 3842 articles with the keywords of Tuberculosis and Diabetes which is ("tuberculosis"[MeSH Terms] OR "tuberculosis"[All Fields]) AND ("diabetes mellitus"[MeSH Terms] OR ("diabetes"[All Fields] AND "mellitus"[All Fields]) OR "diabetes mellitus"[All Fields]). The articles published are selected for last ten 10 years, which was from January 2009 to July 2019. The articles that have been chosen are published in the year 2010 and 2017, respectively. All article type such as clinical trial and review are included. The articles chosen are written in English. Among them, the author has chosen two articles which are most related to the topic. The chosen articles are based upon prevalence, diagnostics and prevention of TB and diabetes mellitus¹⁰.

DISCUSSION
In the introduction, we mentioned that the existence of diabetes and TB is mutual. From the literature reviews that we choose, we also found that the TB rate in patients with diabetes was 23.5%, while the incidence of diabetes in patients with tuberculosis was 12.4%¹¹,¹². However, there was a low uptake of a diagnostic evaluation for TB and confined to the patients that had evident symptoms of TB. So, only diabetic patients suspected of TB will be actively referred. Several programs have also been proposed to screen early TB-diabetes mellitus¹³. Doctors must be well-trained that the diabetic patients receive routine TB screening to carry out other diabetes-associated complications. Moreover, user-fees for the X-ray limit the number of screenings. Based on this problem, cost-free or subsidised will reduce the financial burden, encourage patients to undergo screening and increase the uptake of TB testing. Screening for diabetes in TB patients is best done at the start of TB treatment and registration. Low-cost diabetes testing is recommended, although the results may be slightly skewed, patients are more likely to agree that it is cheap. The laboratories or at the provider clinics provide these tests with the assurance of interventions to obtain data on diabetes screening as part of the TB surveillance system¹⁴,¹⁵. Integrated delivery units provide a solution for diabetes screening, TB diagnosis and TB-diabetes mellitus treatment in a facility that can capture data with supporting systems and monitoring results. The results of the study indicate that patients with TB-diabetes mellitus have a higher risk of adverse diabetes mellitus outcomes, including delayed mycobacterial clearance, relapse and re infection, treatment failure, and even death¹⁶. Two factors are prime suspects, poor glucose control and differences in antibiotic levels of plasma anti- mycoplasma bacteria. Based on the problems stated, we can bring out another question: How to prevent the development of diabetes mellitus in a patient with diabetes¹⁷. Therefore, for patients diagnosed with diabetic TB, the control of blood glucose and effective anti-tuberculosis drugs are the key points and difficulties in the treatment of this disease, as well as the key to prevent the emergence of drug-resistant diabetes mellitus¹⁸. Active control of blood glucose is the key to the treatment of diabetic TB¹⁹. Meanwhile, early diagnosis of TB, early adequate and reasonable anti-TB treatment, strengthens blood glucose monitoring during treatment, and timely evaluation of the treatment effect by reviewing chest radiographs and sputum bacteria. For people with poor glycaemic control, they should consider an appropriate extension of course to 1 year or more. If it progresses to multidrug-resistant TB (Mdr-tb), it is more contagious, more difficult to treat, and the failure rate and mortality are higher. It is essential to develop an appropriate and effective treatment plans for Mdr-tb, and also strengthen the management of patients. These methods are essential to interrupt its transmission²⁰.

CONCLUSION
The high prevalence of diabetes mellitus in low- and middle-income countries where TB is endemic has become one of the issues that should be targeted by the related department. Prevalence, diagnostics and prevention of TB and diabetes mellitus are the topics that needed to be emphasized. Upon the high prevalence of diabetes mellitus and TB, the author has mentioned some actions which are necessary for preventing the occurrence of TB and diabetes mellitus that will be stated below¹⁷. Those actions need to be paid attention by related department so that the prevention for TB-diabetes mellitus can be controlled in well-manner. Furthermore, the author has also stated the relationship between diabetes mellitus and TB. People who are suffering from chronic diseases such as diabetes mellitus will have a weaker immune system²¹. Therefore, they are more likely to progress from latent to active TB. In the research, it was found that the risk of TB is related to the severity of diabetes mellitus. Patients who needed more than 40 units of insulin per day have a double chance to develop TB than those with lower doses²². There are several precautions that are needed to be taken note by TB-diabetes mellitus patients. Poorly controlled diabetes can lead to several complications, including increased susceptibility to infection. For example, infection caused by Mycobacterium Tuberculosis (Mtib). Therefore, diabetes patients need to have regular diabetes control²³ including strict control on their diet and carry out a healthy lifestyle such as exercise regularly and sleep according to time. Besides, the author has also mentioned that diabetes mellitus can increase the risk of successful LTBI in close contacts which can facilitate the progression from LTBI to TB²⁴. In the article, the author has also
mentioned that DM-diabetes mellitus patients have a higher frequency of lower lung lobe infiltrates where Mtb would implant during inhalation. One should further themselves from high infection area where Mtb are endemic. As the fact infections are the cause of worsening diabetic control, but the drugs taken by diabetes patients to treat TB may also weaken the glycemic control of the patients. In the article, the author has also brought up some facts that need to be taken serious. First, overlapping toxicities when treating TB and diabetes mellitus must be handled carefully to avoid subsequent action to the patients. As an example, isoniazid is a drug which is used to treat active TB infections. However, it might cause peripheral neuropathy. Therefore, pyridoxine should be given at the same time to avoid such incidence.

In addition, rifampicin is a potent inducer, which is a host of metabolising enzymes can accelerate the metabolism of drugs given with rifampicin. It can cause hyperglycaemia when treated with oral hypoglycaemic drugs directly or indirectly and leading to reduced treatment effects. For example, sulfonyl urasare oral hypoglycaemic drugs which is usually used for Type 2 diabetic patients. Other treatment such as rosiglitazone and repaglinide should also be paid more attention when treating with rifampicin. This is because rifampicin can reduce the plasma concentrations of the mentioned drugs by 54% and 31% respectively.

TB is an infectious disease which can be transmitted through the air. Thus, one needs to be cautious when exposing to a high risk area. Wearing a mask would be an ideal way to prevent infection. However, the best preventing way is to avoid an area with the high spreading of TB, especially diabetes patients. They need to have full protection from TB in order to prevent any infection.

As a conclusion, TB-diabetic patients need to pay more attention to their lifestyle. All the risk factors should be avoided to prevent any incidences or to worsening of the disease. The associated department should also educate the public on the prevention of diseases. Campaign and social media are the easiest and effective way of reducing the prevalence of TB and diabetes mellitus.
